

Lab report no – 03

Lab report name : Thread on operating system

IT - 17010

Objective:- A fundamental unit of CPU utilization that forms the basis of multithreaded computer systems. To discuss the APIs for the Pthreads, Windows and java thread libraries. To cover operating system support for threads in Windows and Linux.

Thread:-

- A thread is a stream of execution throughout the process code having its program counter which keeps track of lists of instruction to execute next, system registers which bind its current working variables. Threads are also termed as lightweight process. Each thread has different states. Each thread has

1. A program counter
2. A register set
3. A stack space

Types Of Threads:-Threads are implemented in following two ways.

1. User Level Threads
2. Kernel Level Threads

User Level thread (ULT) –User Level Thread is implemented in the user level library, they are not created using the system calls. Thread switching does not need to call OS and to cause interrupt to Kernel.

Advantages of ULT –

- Simple representation since thread has only program counter, register set, stack space.
- Simple to create since no intervention of kernel.
- Thread switching is fast since no OS calls need to be made.

Disadvantages of ULT –

- No or less co-ordination among the threads and Kernel.
- If one thread causes a page fault, the entire process blocks.

Kernel Level Thread (KLT) – Instead of thread table in each process, the kernel itself has thread table (a master one) that keeps track of all the threads in the system. In addition kernel also maintains the traditional process table to keep track of the processes.

Advantages of KLT –

- Since kernel has full knowledge about the threads in the system, scheduler may decide to give more time to processes having large number of threads.
- Good for applications that frequently block.

Disadvantages of KLT –

- Slow and inefficient.
- It requires thread control block so it is an overhead.

Implementation of Threads:-The ability to share the same address space and data is essential for some applications. There are no resources attached to threads. Processes are difficult to create and destroy but threads, on the other hand, can be easily created and destroyed. Creating a thread is about 100x faster than creating a process. The thread has program counter (pc) to keep the track of the instruction to be executed next.

Threads are scheduled for the implementation or execution on CPU.

There are four states of a thread:

1. Running
2. Blocked
3. Ready
4. Terminated

There are two ways of implementing a thread package:

1. In user space
2. In kernel

Threads implementation in the user space:-In this model of implementation, the threads package entirely in user space, the kernel has no idea about it. A user-level threads package can be executed on an operating system that doesn't support threads and this is the main advantage of this implementation model i.e. Threads package in user space.

Threads implementation in the kernel:-In this method of implementation model, the threads package completely in the kernel. There is no need for any runtime system. To maintain the record of all threads in the system a kernel has a thread table. A call to the kernel is made whenever there is a need to create a new thread or destroy an existing thread. In this, the kernel thread table is updated.

Other two methods are as follows:

- Hybrid implementation
- Scheduler activation

Hybrid implementation

In this implementation, there is some set of user-level threads for each kernel level thread that takes turns by using it.

Scheduler activation

The objective of this scheduler activation work is to replicate the working or function of kernel threads, but with higher performance and better flexibility which are usually related to threads packages which are implemented in userspace.

Pop-up threads

In this system, a new thread is created just to handle the message as soon as the arrival of a message takes place and thus it is called pop up thread.

Conclusion:-An operating system is needed in order to use various applications on your computer and wireless devices. Without iOS and its continual upgrades there would be no way to operate today's trend setting wireless Apple devices.
